FOUNDATIONS & MATERIALS BRANCH

ATTACHMENT #1

Based upon the visual inspection and past performance of the dam, the condition of the dam is generally good. The dam appears stable with no signs of movement or settlement. Visual inspection did not disclose an unstable condition due to seepage through the foundation or instability of the dam foundation or abutments. (This is a composite of 3.1.a, 3.2 and 6.1.a). Use this statement in Brief Assessment page ia and 7.1.a.

Lower Housatonic River Basin

Great Hill Reservoir Dam

ABSTRACT (Continue on reverse side if necessary and identify by block number)

The dam is a 210 ft. long concrete gravity structure with a central concrete round crested ogee weir 40 ft. in length, 3.0 ft. below top of dam. The dam has a maximum height of 41 ft. and a crest width of 6.0 ft. The gate house is adjacent to the left side of the spillway. The regulating outlets include a 16 inch direct supply main and a 20 inch low level intake, which outlets at the toe of the spillway. The rural drainage area is 2.64 square miles. The perimeter of the reservoir is heavily forested. Some minor development upstream along Fourmile Brook is occuring.

The dam is a 210 feet long concrete gravity structure with a central concrete round crested ogee weir 40 feet in length, 3.0 feet below top of dam. The dam has a maximum height of 41' feet and a crest width of 6.0 feet. The gate house is adjacent to the left side of the spillway. regulating outlets include a 16 inch direct supply main and a 20 inch low level intake, which outlets at the toe of the The rural drainage area is 2.64 square miles. spillway. The perimeter of the reservoir is heavily forested. along Fourmile minor development upstream Brook Approximately one mile downstream of the dam there exists several houses and a state road.

Based upon the visual inspection and past performance of the dam, the condition of the dam is generally good. The dam appears stable with no signs of movement or settlement. Visual inspection did not disclose an unstable condition due to seepage through the foundation or instability of the dam foundation or abutments.

Based upon the size (intermediate) and hazard (high) classification in accordance with the Corps guidelines the test flood will be equal to the Probable Maximum Flood.

Based upon our hydraulic computations the spillway capacity is 810 cubic feet per second, which is equivalent to approximately 13 percent of the Test Flood. Peak inflow

to the reservoir is 6,600 cubic feet per second; peak outflow (Test Flood) is 6,400 cubic feet per second with the dam being overtopped by 3.6 feet. The spillway is not adequate and will pass only 810 cfs at elevation 290 (top of The average downstream flood stage along Fourmile Brook to its confluence with the Housatonic River will be 10 feet for an outflow of 13,300 cubic feet per second. major impact of such a flood stage would be to wash out the bridge at Route 34 and another masonry arch located 100 feet upstream of Route 34. Before being washed out, back up would undoubtedly occur effecting a day nursery and at least one dwelling. Thus damage to life and property can occur in the vicinty of Route 34, on the east bank of the Housatonic River, one mile below the dam.

It is our opinion that further studies with regards to the geotechnical nature of the soil/rock at the abutments, dam base and key and a more refined hydrologic study be performed. Also a more detailed field survey to determine location and magnitude of overflow spillage will be required. All of the above should be done within one year of the owner's receipt of this Phase I Inspection Report.

After this information has been reviewed it can be determined whether or not corrective measures would be required.

This Phase I Inspection Report on Great Hill Reservoir Dam has been reviewed by the undersigned Review Board members. In our opinion, the reported findings, conclusions, and recommendations are consistent with the Recommended Guidelines for Safety Inspection of Dams, and with good engineering judgment and practice, and is hereby submitted for approval.

CHARLES G. TIERSCH, Chairman Chief, Foundation and Materials Branch Engineering Division

FRED J. RAVENS, Jr., Member Chief, Design Branch Engineering Division

SAUL C. COOPER, Member Chief, Water Control Branch Engineering Division

APPROVAL RECOMMENDED:

JOE B. FRYAR Chief, Engineering Division

PREFACE

This report is prepared under guidance contained in the Recommended Guidelines for Safety Inspection of Dams, for Phase I Investigations. Copies of these guidelines may be obtained from the Office of Chief of Engineers, Washington, D.C. 20314. The purpose of a Phase I Investigation is to identify expeditiously those dams which may pose hazards to human life or property. The assessment of the general condition of the dam is based upon available data and visual inspection. Detailed investigation, and analyses involving topographic mapping, subsurface investigations, testing, and detailed computational evaluations are beyond the scope of a Phase I Investigation; however, the investigation is intended to identify any need for such studies.

In reviewing this report, it should be realized that the reported condition of the dam is based on observations of field conditions at the time of inspection along with data available to the inspection team. In cases where the reservoir was lowered or drained prior to inspection, such action, while improving the stability and safety of the dam, removes the normal load on the structure and may obscure certain conditions which might otherwise be detectable if inspected under the normal operating environment of the structure.

It is important to note that the condition of a dam depends on numerous and constantly changing internal and external conditions, and is evolutionarly in nature. It would be incorrect to assume that the present condition of the dam at some point in the future. Only through continued care and inspection can there be any chance that unsafe conditions be detected.

Phase I inspections are not intended to provide detailed hydrologic and hydraulic analyses. In accordance with the established Guidelines, the Spillway Test Flood is based on the estimated "Probable Maximum Flood" for the region (greatest reasonably possible storm runoff), or fractions there of. Because of the magnitude and rarity of such a storm event, a finding that a spillway will not pass the test flood should not be interpreted as neccessarily posing a highly inadequate condition. The test flood provides a measure of relative spillway capacity and serves as an aid in determining the need for more detailed hydrologic and hydraulic studies, considering the size of the dam, its general condition and the downstream damage potential.

CONNECTICUT

DATE 5/25/78

CE # 27 531 GA

PAGE____Viii

PHASE I INSPECTION REPORT

GREAT HILL RESERVOIR DAM

SECTION I

PROJECT INFORMATION

1.1 General

- a. Authority Public Law 92-367, August 8, 1972, authorized the Secretary of the Army, through the Corps of Engineers, to initiate a National Program of Dam Inspection throughout the United States. The New England Division of the Corps of Engineers has been assigned the responsibility of supervising the inspection of dams within the New England Region. Cahn Engineers has been retained by the New England Division to inspect and report on selected dams in the southwestern state of Connecticut. Authorization and notice to proceed were issued to Cahn Engineers, Inc. under a letter of April 26, 1978 from Ralph T. Garver, Colonel, Corps of Engineers. Contract No. DACW33-78-C-0310 has been assigned by the Corps of Engineers for this work.
- b. Purpose of Inspection Program The purposes of the program are to:
 - (1) Perform technical inspection and evaluation of non-Federal dams to identify conditions requiring correction in a timely manner by non-Federal interest.
 - (2) Encourage and prepare the States to quickly initiate effective dam inspection programs for non-Federal dams.
 - (3) To update, verify and complete the National Inventory of Dams.
- c. Scope of Inspection Program The scope of this Phase I inspection report includes:
 - (1) Gathering, reviewing and presenting all available data as can be obtained from the owners, previous owners, the state and other associated parties.

- (2) A field inspection of the facility detailing the visual condition of the dam, embankments and appurtenant structures.
- (3) Computation concerning the hydraulic and hydrology of the facility and its relationship to the calculated flood through the existing spillway.
- (4) An assessment of the condition of the facility and corrective measures required.

It should be noted that this report does not pass judgement on the safety or stability of the dam other than on a visual basis. The intent of the inspection program is to alert concerned parties of apparent necessary corrective action requirements or further investigation recommendations.

1.2 Description of Project

- a. Description of Dam and Appurtenances The dam is a 210 feet long concrete gravity structure with a central concrete round crested ogee weir 40 feet in length. The dam has a maximum height of 41.0 feet and a crest width of 6.0 feet. The gate house is adjacent to the left side of the spillway. The regulating outlets include a 16 inch direct supply main and a 20 inch low level intake which outlets at the toe of the spillway. The rural drainage area is 2.64 square miles. The perimeter of the reservoir is heavily forested. Some minor development upstream along Fourmile Brook is occurring.
- b. Location The dam is located on Fourmile Brook in a rural area in the the Town of Seymour, County of New Haven, State of Connecticut. The dam is shown on the Southbury U.S.G.S. Quadrangle Map having coordinates of longitude W 73 07'56" and latitude N 41° 22'32".
- c. <u>Size Classification</u> Intermediate (Height 41.0 Ft), (Storage 378 Acre Ft.).
- d. <u>Hazard Classification</u> High (Category I) State Highway Route 34 and several houses located 4500 ft. downstream. A ten foot high flood stage caused by a potential dam failure would wash out the bridge at Route 34 and another masonry arch 100' upstream of it. Roads at these are 15 to 16' above the streambed. Before being washed out, backup would undoubtally occur. The day nursery and at

least one home, which are 13 feet above the streambed, would get flooded to some degree. Thus damage to life and property can potentially occur in the vicinity of Route 34, on the east bank of the Housatonic river.

- e. Ownership Ansonia-Derby Water Company
 230 Beaver Street
 Ansonia, Connecticut 06401
 Mr. Fred Elliott (203) 735-1888
- f. Purpose of Dam Public Water Supply (at present no longer used does not meet current water quality criteria). Local sporting clubs are allowed to use the reservoir area at this time.
- g. Design and Construction History The dam is believed to have been originally constructed in 1909 for the Birmingham Water Company. The engineer and contractor are not known. At an unknown later date the top of the dam and the downstream face were covered with a thin (1" to 4") mortar facing. The dam's present appearance does not suggest any other raisings or modifications.
- h. Normal Operational Procedures No formal operational procedures exist for this dam due to the present water quality.

1.3 Pertinent Data

- a. Drainage Area 2.64 square miles.
- b. <u>Discharge at Damsite</u> Maximum Flood Not Known. Total spillway capacity at maximum pool elevation 810 cfs.
 - c. Elevations (Ft. above MSL, U.S.G.S. Datum)
 Top of Dam: 293
 Spillway Crest: 290
 Streambed at Centerline of Dam: 256

Both are manually operated from the gatehouse on the upstream face of the dam.

SECTION 2: ENGINEERING DATA

2.1 Design

- a. Available Data The available data consists of a drawing supplied by the owner and Inventory Data sheet provided by the State of Connecticut and the owner. See Appendix B for available existing data.
- b. <u>Design Features</u> The existing drawing indicates the design features stated previously herein.
- c. <u>Design Data</u> There were no engineering values, assumptions, test results or calculations available for the original construction.

2.2 Construction

- a. Available Data The one existing drawing, included in Appendix B, indicates the dam substantially as constructed.
- b. Construction Considerations No construction consideration information was available.

2.3 Operations

Daily lake levels between 1973 and 1977 had been taken on this dam until the water quality was judged inadequate. The maximum known water over the spillway was 4 inches on December 2, 1974. This information is available at the owners office.

2.4 Evaluation

- a. Availability Existing data was provided by the State of Connecticut and the owner. The owner representative made the operations available for visual inspection.
- b. Adequacy Due to the limited amount of detailed engineering data available (dam purchased from Birmingham Water Company 1973 ±, transfer of records minimal) the final assessment of this investigation must be based primarily on visual inspection, performance history and hydraulic/hydrologic assumptions.
- c. Validity The engineering data substantially agrees with the field observations.

SECTION 3: VISUAL INSPECTION

3.1 Findings

- a. General The appearance of the dam is generally good, except for spalling of the parged concrete face.
- b. Dam Bedrock outcrops occur along the right side of the lower stream for more than 200 ft downstream of the spillway.

Examination of the outcrops revealed that the bedrock in the vicinity is consistent with what has been previously described in the USGS bedrock geology maps as the Collinsville Formation. The rock exposed in the outcrops can be described as hard, medium gray, fine to medium grained schistose gneiss. The rock exhibits well-developed foliation, accounting for its slabby character, and is predominantly gneissic in texture. The texture occasionally exhibits a segregation of biotite/muscovite micas from quartz/feldspar in the form of distinct banding. Quartz is abundant and occasionally occurs as lenses or elliptical pods (Augen Structure).

The trend of foliation was measured at several locations within about 200 ft of the dam and strikes N70 to 73° east and dips to the southeast 16 to 22°. The predominant joint pattern parallels foliation and tends to occur along planes of mica concentrations at 3 to 6 inch intervals. Minor jointing occurs perpendicular to foliation.

There were no seeps observed at the base of the dam. At the base of the right abutment, a small seep of clear water was observed through the exposed bedrock joints about 20 ft. downstream of the dam.

The abutments downstream of the dam appear stable with no indications of sloughing or significant erosion. Since the reservoir was at about the level of the spillway crest, the abutments upstream of the dam could not be observed.

c. Appurtenant Structures - The channel immediately downstream of the dam has stone retaining walls on both left and right banks. The walls are in good condition, except at the downstream end of both walls where a short section of the walls have collapsed.

- d. Reservoir The topography surrounding the reservoir slopes rapidly to the water. The shoreline is heavily forested. Sedimentation from winter sanding of roads washes into the reservoir at its northern end.
- e. <u>Downstream Channel</u> The downstream channel is the natural streambed. There is no evidence of slope instability or of substantial obstructions to flow in the channel.

3.2 Evaluation

The visual inspection did not disclose any findings indicating an unstable condition due to seepage through the foundation or to instability of the dam foundation or of the abutments downstream of the dam. The inspection team did not observe a downstream bulge as described in Appendix B.

SECTION 4: OPERATIONAL PROCEDURES

4.1 Regulating Procedures

No regulating procedures exist for this dam. Due to water quality requirements this reservoir has been taken out of service.

4.2 Maintenance of Dam

The dam is visited at least once a week to check on vandalism. Maintenance when needed is reported during these visits.

4.3 Maintenance of Operating Facilities

The maintenance of the operating facilities is on an as needed basis. The low level valve is greased once a year and inspected and operated at least twice a year in the spring and fall.

4.4 Description of Any Warning System in Effect

No formal warning system is in effect. The dam operator reports emergency situations directly to his supervisor. Depending on the situation the supervisor either contacts his engineers or calls the State Police and Seymour Police Departments to alert downstream residents.

4.5 Evaluation

A regular maintenance program should be established.

SECTION 5: HYDRAULIC/HYDROLOGIC

5.1 Evaluation of Features

- a. <u>Design Data</u> No computations could be found for the original dam construction.
- b. Experience Data From late fall to early summer water flows over the spillway. The maximum water level over the spillway was recorded to be 4 inches on December 2, 1974. Prior to and during our field inspection the following sequence of events occurred which exhibit the ability of the reservoir to be drained during emergency situations.
 - (1) 5/24/78 PM Ansonia-Derby Water Company opens blow off a small amount so as to lower water level approximately 1" to 2" to be at or below spillway elevation for the next day.
 - (2) 5/24/78 PM to 5/25/78 AM Water outletting while precipitation produces 2.5+ inches.
 - (3) 5/25/78 7:30 AM 1 hour before we arrive, Ansonia-Derby opens valve additional amount to get water below spillway. Elevation prior to our arrival is unknown.
 - (4) 5/25/78 8:30 AM Water level below spillway when we arrived. We observed blow off flowing and then valve was shut off.
- c. <u>Visual Observations</u> On the date of the inspection the spillway was clear and unobstructed.
- d. Overtopping Potential The test flood for this high hazard intermediate size dam is equal to the Probable Maximum Flood (PMF) of 6400 cfs.

Based upon our hydraulic computations, the spillway capacity is 810 cfs (Appendix D-3). Based upon "Preliminary Guidance for Estimating Maximum Probable Discharges" dated March 1978, peak inflow to the reservoir is 6,600 cfs (Appendix D-5); peak outflow for the test flood is 6,400 cfs with the dam overtopped 3.6' (Appendix D-7).

e. Spillway Adequacy - The spillway is not adequate. It will pass only approximately 13 percent of the Test Flood at elevation 290 (top of dam).

SECTION 6: STRUCTURAL STABILITY

6.1 Evaluation of Structural Stability

a. <u>Visual Observations</u>

1. Embankment - The dam appears stable with no signs of movement or settlement.

2. Appurtenant Structures

- a. The spillway is in good condition with no indications of structural problems.
- b. The valve chamber is in good condition with no indication of structural problems.
- b. Design and Construction Data The design and construction data is insufficient to formally evaluate the stability of the dam.
- c. Operating Records None of the available records indicates that foundation stability problems have developed in the past 69 years in which the dam has been in existence and in particular during the September, 1938 and August, 1955 floods.
- d. <u>Post Construction Changes</u> The only post construction work in evidence is of maintenance nature. This has apparently not affected the stability of the dam.
- e. Seismic Stability This dam is in Seismic Zone 1 and hence does not have to be evaluated for Seismic Stability, according to the USCE Recommended Guidelines.

7.1 Dam Assessment

- a. Condition Based upon our hydraulic computations the spillway capacity is 810 cubic feet per second. Based upon "Preliminary Guidance for Estimating Maximum Probable Discharge" dated March 1978, peak inflow to the reservoir is 6,600 cubic feet per second; peak outflow is 6,400 cubic feet per second with the dam being overtopped by 3.6 feet. The spillway is not adequate and will pass only 13% of the peak outflow. The average downstream flood stage along Fourmile Brook to its confluence with the Housatonic River will be 10 feet for a reach outflow of 13,300 cubic feet per second. The major impact of such a flood stage would be to wash out the bridge at Route 34 and another masonry arch located 100 feet upstream of Route 34. Before being washed out, backup would undoubtedly occur effecting a day nursery and at least one dwelling. Thus damage to life and property can occur in the vicinity of Route 34, on the east bank of the Housatonic River, one mile below the dam.
- b. Adequacy of Information There is not enough available information to evaluate the stability of the dam other than by visual inspection. In particular, the foundation stability of the dam cannot be evaluated without extensive data on the quality of bedrock immediately under the dam.
- c. <u>Urgency</u> The recommendations and remedial measures presented in Sections 7.2 and 7.3 should be implemented within one year of the owner's reciept of this Phase I Inspection Report.
- d. Need for Additional Information There is a need for additional information as described in Section 7.2.

7.2 Recommendations

1. It is our opinion that further studies with regards to the geotechnical nature of the soil/rock at the abutments, dam base, and key and a more refined hydrologic study be performed. Also a more detailed field survey to determine location and magnitude of overflow spillage will be required. Depending on the results of those studies, items 2 and 3 below may be required.

- 2. Provide capability for passing the Test Flood without causing dam failure or significant downstream damage.
- 3. Implement surface improvements which may be required at the abutments of the dam to minimize erosion caused by water flowing over the dam.

7.3 Remedial Measures

- a. Alternatives This study has identified no practical alternatives to the recommendations.
- b. Operation and Maintenance Procedures An operation and maintenance plan should be instituted to include:
 - Repair of spalled areas along entire length of dam including the crest and up and downstream faces; while establishing a regular maintenance program to resurface reoccurring spalled areas of the dam.
 - Inspection of the dam at least once every 2 years by an inspector qualified in dam inspection.
 - 3. Opening of the low level outlet valve twice a year for a minimum of 6 hours. This would assure that it is operable and that the inlet doesn't clog with sediment.
 - 4. Round the clock surveillance should be provided by the owner during periods of unusually heavy precipitation. The owner should develop a formal system with local officials for warning downstream residents in case of an emergency.

ON MAXIMUM PROBABLE DISCHARGES

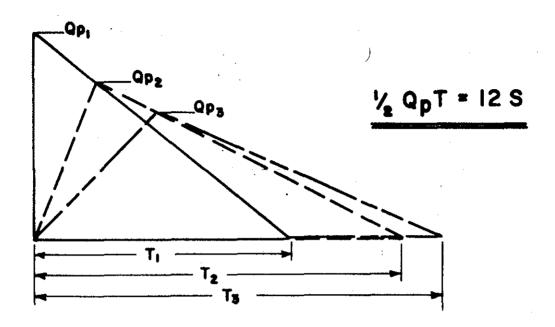

- STEP 1: Determine Peak Inflow (Qp1) from Guide; Curves.
- STEP 2: a. Determine Surcharge Height To Pass "'Qp1".
 - b. Determine Volume of Surcharge (STOR1) In Inches of Runoff.
 - c. Maximum Probable Flood Runoff In Ne / England equals Approx. 19", Therefore

$$Qp2 = Qp1 \times (1 - \frac{STOR1}{19})$$

- STEP 3: a. Determine Surcharge Height and "STOR2" To Pass "Qp2"
 - b. Average "STOR1" and "STOR2" and Determine Average Surcharge and Resulting Peak Outflow "Qp3".

₽-5

"RULE OF THUMB" GUIDANCE FOR ESTIMATING DOWNSTREAM DAM FAILURE HYDROGRAPHS

STEP 1: DETERMINE OR ESTIMATE RESERVOIR STORAGE (S) IN AC-FT AT TIME OF FAILURE.

STEP 2: DETERMINE PEAK FAILURE OUTFLOW (Qp1).

W_b= BREACH WIDTH - SUGGEST VALUE NOT GREATER THAN 40% OF DAM LENGTH ACROSS RIVER AT MID HEIGHT.

Yo = TOTAL HEIGHT FROM RIVER BED TO POOL LEVEL AT FAILURE.

STEP 3: USING USGS TOPO OR OTHER DATA, DEVELOP REPRESENTATIVE STAGE-DISCHARGE RATING FOR SELECTED DOWNSTREAM RIVER REACH.

STEP 4: ESTIMATE REACH OUTFLOW (Q_{p2}) USING FOLLOWING ITERATION.

- A. APPLY Q_{p1} TO STAGE RATING, DETERMINE STAGE AND ACCOPMANYING VOLUME (V₁) IN REACH IN AC-FT. (NOTE: IF V₁ EXCEEDS 1/2 OF S, SELECT SHORTER REACH.)
- B. DETERMINE TRIAL Qp2.

- c. COMPUTE v_2 USING Q_{p2} (TRIAL).
- D. AVERAGE V_1 AND V_2 AND COMPUTE Q_{p2} . $Q_{p2} = Q_{p1} \left(1 \frac{V_{max}}{5} \right)$

STEP 5: FOR SUCCEEDING REACHES REPEAT STEPS 3 AND 4.

roject	GREAT HILL	DAM	Sheat of
mputed	By HM/CRG		Date 9/8/78
eld Book	Ref.		Revisions

SPILLWAY RATING CURVE

Q= 156 H3/2 + 405 (H-3) 3/2 + 37.8 (H-3) 5/2

Q = Flow (cfs)

### Sahn Engineers Inc.

Consulting Engineers

'rojec	:t	GREAT HILL	RESERVOIR DAM	Sheet of
ompi	ited E	Ву	Checked By	Date
ield	Bock	Ref	Other Refs	Revisions

### NOTE:

THESE COMPUTATIONS HAVE BEEN PERFORMED BASED UPON A DAM BREACH WITH A SURCHARGED WATER SURFACE ELEVATION. IN ACCORDANCE WITH NORMAL CORPS PROCEDURES, COMPUTATIONS ARE PERFORMED BASED UPON A WATER SURFACE ELEVATION AT THE TOP OF THE DAM. A DAM BREACH WITH THE WATER SURFACE AT THE TOP OF THE DAM AND WITHOUT HEAVY DOWN-STREAM CHANNEL FLOW COULD BE MORE CRITICAL THAN A DAM BREACH WITH A SURCHARGE. THE DIFFERENCE, IN THIS CASE, IS NOT SUBSTANTIAL.
